

# Package: pkpd.Release (via r-universe)

June 1, 2026

**Type** Package

**Title** Model Fitting and Simulation for Drug Release Kinetics and PK/PD

**Version** 0.1.0

**Author** Paul Angelo C. Manlapaz [aut, cre] (ORCID:

<<https://orcid.org/0000-0002-1203-2064>>)

**Maintainer** Paul Angelo C. Manlapaz <pacmanlapaz@gmail.com>

**Description** Provides a comprehensive framework for model fitting and simulation of drug release kinetics, pharmacokinetics (PK), and pharmacodynamics (PD). The package implements widely used mechanistic and empirical models for in vitro drug release, including zero-order, first-order, Higuchi, Korsmeyer-Peppas, Hixson-Crowell, and Weibull models. Pharmacokinetic functionality includes linear and nonlinear functions for one- and two-compartment models for intravenous bolus and oral administration, Michaelis-Menten kinetics, and non-compartmental analysis (NCA). Pharmacodynamic and dose-response modeling is supported through Emax-based models, including stimulatory (sigmoid Emax) and inhibitory (sigmoid I<sub>max</sub>) Hill models, four- and five-parameter logistic models, as well as median toxic dose (TD50) and lethal dose (LD50) models. The package is intended to support parameter estimation, simulation, and model comparison in pharmaceutical research, drug development, and pharmacometrics education. For more details, see Gabrielsson & Weiner (2000) <ISBN:9186274929>, Holford & Sheiner (1981) <[doi:10.2165/00003088-198106060-00002](https://doi.org/10.2165/00003088-198106060-00002)>, and Manlapaz (2025) <[doi:10.32614/CRAN.package.adsoRptionCMF](https://doi.org/10.32614/CRAN.package.adsoRptionCMF)>.

first\_order\_release    *First-Order Drug Release Kinetic Model*

---

## Description

Fits experimental cumulative drug release data to a first-order kinetic model using linear regression on the log-transformed unreleased fraction. The function supports optional grouping (formulation/batch) and pH-dependent analysis. It can generate plots with straight lines and annotations for first-order rate constant ( $k_1$ ), intercept, coefficient of determination ( $R^2$ ), and time required for 50-percent drug release ( $t_{50}$ ).

**Arguments**

data	A data frame containing experimental drug release data.
time_col	Character string specifying the column name for time.
log_remain_col	Column name for log cumulative percent drug remaining.
group_col	Optional character string specifying a column for grouping (e.g., formulation/batch).
pH_col	Optional character string specifying a column containing pH values.
plot	Logical; if TRUE, generates a plot of experimental data with first-order fitted curves.
annotate	Logical; if TRUE, annotates the plot with $k_1$ , intercept, $R^2$ , and $t_{50}$ (only if $\leq 2$ groups).

**Value**

A list containing:

fitted_parameters	Data frame with $k_1$ , intercept, $R^2$ , and $t_{50}$ values for each group or pH condition.
data	The processed data used for model fitting and plotting.

 higuchi\_release

*Higuchi Drug Release Kinetic Model*

---

## Description

Fits experimental cumulative drug release data to the Higuchi square-root kinetic model using linear regression of cumulative percent drug released versus square root of time. The function supports optional grouping variables (e.g., formulation, batch) and optional pH-dependent analysis. It generates publication-quality plots with experimental curves, fitted Higuchi straight lines, and annotations for Higuchi release constant (kH), intercept, coefficient of determination ( $R^2$ ), and the time required for 50-percent drug release (t50).

## Arguments

data	A data frame containing experimental drug release data.
sqrt_time_col	Character string specifying the column name for square root of time.
release_col	Character string specifying the column name for cumulative percent drug released.
group_col	Optional character string specifying a grouping variable (e.g., formulation, batch). Default is NULL.
pH_col	Optional character string specifying a column containing pH values. If provided, Higuchi models are fitted separately for each pH.
plot	Logical; if TRUE, generates a plot (default = TRUE).
annotate	Logical; if TRUE, annotates the plot with kH, intercept, $R^2$ , and t50 values (only if $\leq 2$ groups).

## Value

A list containing:

fitted\_parameters A data frame with kH, intercept,  $R^2$ , and t50 values for each group or pH condition.

data The processed data used for fitting and plotting.

hixson\_crowell\_model *Hixson-Crowell Drug Release Kinetic Model*

---

## Description

Fits experimental cumulative drug release data to the Hixson-Crowell cube-root model, which describes drug release from systems where dissolution occurs with a change in surface area and particle diameter over time. The model is based on a linear regression of  $(W_0^{1/3} - W_t^{1/3})$  versus time.

The function assumes that the initial drug amount ( $W_0$ ) is known and that the remaining drug amount ( $W_t$ ) can be calculated from cumulative percent drug remaining data. It supports optional grouping variables (e.g., formulation, batch) and optional pH-dependent analysis. The function generates publication-quality plots with experimental data points, fitted Hixson-Crowell straight lines, and annotations for the Hixson-Crowell rate constant ( $k_{HC}$ ), intercept, coefficient of determination ( $R^2$ ), and the time required for 50-percent drug release ( $t_{50}$ ).

Model:

$$W_0^{1/3} - W_t^{1/3} = k_{HC} * t$$

where: -  $W_0$  is the initial amount of drug -  $W_t$  is the remaining amount of drug at time  $t$  -  $k_{HC}$  is the Hixson-Crowell dissolution rate constant

The Hixson-Crowell model is applicable to dosage forms where drug release is governed by erosion or dissolution with a decreasing surface area (e.g., tablets, pellets).

**Arguments**

data	A data frame containing experimental drug release data.
time_col	Character string specifying the column name for time (minutes).
remain_col	Character string specifying the column name for cumulative percent drug remaining.
group_col	Optional character string specifying a grouping variable (e.g., formulation, batch).
pH_col	Optional character string specifying a column containing pH values.
plot	Logical; if TRUE, generates a plot with fitted Hixson-Crowell lines.
annotate	Logical; if TRUE, annotates the plot with kHC, intercept, R <sup>2</sup> , and t50 (only if <= 2 groups).

**Value**

A list containing:

`fitted_parameters` Data frame with Hixson-Crowell parameters (kHC, intercept), coefficient of determination (R<sup>2</sup>), and t50 for each group.

`data` Processed data used for model fitting and plotting.

---

 korsmeyer\_peppas\_model

*Korsmeyer-Peppas Drug Release Kinetic Model*

---

## Description

Fits experimental cumulative drug release data to the Korsmeyer-Peppas model using log10-transformed fraction released vs. log10-transformed time. The function automatically normalizes cumulative percent drug release to fraction (0-1) by default and removes  $t = 0$ . In addition, the function supports optional grouping variables (e.g., formulation, batch) and optional pH-dependent analysis. It generates publication-quality plots with experimental curves, fitted Korsmeyer-Peppas straight lines, mechanism table, and annotations for Korsmeyer-Peppas release constant (kKP), release exponent (n), intercept, coefficient of determination ( $R^2$ ), and the time required for 50-percent drug release (t50).

Users can toggle 'normalize = TRUE/FALSE' to use fraction (0-1) or raw percent drug release.

Model:  $\log_{10}(Mt/M_{\infty}) = \log_{10}(k) + n * \log_{10}(t)$

The release exponent, n, indicates the drug release mechanism: -  $n = 0.5$  : Fickian diffusion -  $0.5 < n < 1$  : Non-Fickian (anomalous) diffusion -  $n = 1$  : Case II transport (zero-order release) -  $n > 1$  : Super Case II transport

## Arguments

data	A data frame containing experimental cumulative percent drug release.
time_col	Character string specifying the column name for time (minutes).
release_col	Character string specifying the column name for cumulative percent drug release.
group_col	Optional character string specifying a grouping variable (e.g., formulation, batch).
pH_col	Optional character string specifying a column containing pH values.
plot	Logical; if TRUE, generates a plot with fitted Korsmeyer-Peppas lines.
annotate	Logical; if TRUE, annotates the plot with kKP, n, intercept, $R^2$ , and t50 (only if $\leq 2$ groups).
normalize	Logical; if TRUE (default), normalizes cumulative percent release to fraction (0-1). If FALSE, retains original percent values.

## Value

A list containing:

fitted\_parameters Data frame with kKP, n, intercept,  $R^2$ , and t50 for each group.

data Processed data used for fitting and plotting.

 ld50\_model

*Lethal Dose 50 (LD50) Pharmacodynamic Model*

---

## Description

Fits quantal mortality data to a logistic dose-response model to estimate the Lethal Dose 50 (LD50), defined as the dose expected to cause death in 50

The model uses binomial logistic regression and supports optional grouping (e.g., species, sex, strain, formulation) and stratification by experimental conditions (e.g., exposure route, duration).

In addition to LD50 estimation, the model provides the following interpretable parameters:

- **Slope:** Represents the steepness of the dose-mortality relationship. A larger slope indicates a rapid transition from survival to lethality with increasing dose (high sensitivity and narrow safety margin), whereas a smaller slope reflects a more gradual increase in mortality, suggesting greater inter-individual variability in response.
- **Intercept:** Represents the baseline log-odds of mortality at zero dose. A strongly negative intercept indicates negligible background mortality, while a positive intercept suggests mortality occurring in the absence of administered dose, which may reflect experimental bias, underlying disease, or study design limitations.
- **LD50 95% Confidence Interval:** An approximate 95 interval for the LD50, computed using the delta method. This provides an uncertainty range around the estimated dose causing 50

- **McFadden Pseudo-R<sup>2</sup>**: A likelihood-based measure of model goodness-of-fit that quantifies the improvement of the fitted model over a null (intercept-only) model. Values between 0.1 and 0.2 indicate acceptable biological fit, while values above 0.3 suggest a strong and reliable dose-mortality relationship.

The function can generate dose-response plots with fitted curves and annotate LD50, slope, intercept, LD50 confidence intervals, and McFadden pseudo-R<sup>2</sup> values.

### Arguments

<code>data</code>	A data frame containing mortality response data.
<code>dose_col</code>	Character string specifying the administered dose column.
<code>response_col</code>	Character string specifying the binary mortality outcome (0 = alive, 1 = dead).
<code>group_col</code>	Optional character string specifying a grouping variable.
<code>condition_col</code>	Optional character string specifying an experimental condition.
<code>plot</code>	Logical; if TRUE, generates dose-mortality plots.
<code>annotate</code>	Logical; if TRUE, annotates the plot with LD50, confidence intervals, and model parameters (only if $\leq 2$ groups).

### Value

A list containing:

`fitted_parameters` Data frame with LD50, 95% confidence intervals, slope, intercept, and pseudo-R<sup>2</sup> values for each group.

`data` The processed data used for model fitting and plotting.

logistic\_4pl

4PL Logistic Dose-Response Model (Emax/Imax)

---

## Description

Fits pharmacodynamic dose-response data to a 4-parameter logistic (4PL) model using nonlinear least squares regression.

The model can handle **both increasing (Stimulatory / Emax)** and **decreasing (Inhibitory / Imax)** dose-response curves automatically.

The 4PL model generalizes the Hill/Sigmoid model:

$$E = E_{min} + \frac{E_{max} - E_{min}}{1 + (EC_{50}/D)^n} \quad \text{for increasing curves}$$

$$E = E_{min} + \frac{E_{max} - E_{min}}{1 + (D/IC_{50})^n} \quad \text{for decreasing curves}$$

Key features: \* Automatically detects increasing vs decreasing responses \*  $E_{min}$  = minimum response (floor) \*  $E_{max}$  = maximum response (ceiling) \*  $EC_{50}/IC_{50}$  = dose producing half-maximal effect \*  $n$  = Hill coefficient (steepness) \* Symmetric sigmoid curve about midpoint

**Arguments**

data	A data frame containing dose-response experimental data.
dose_col	Character string specifying the column name for dose.
response_col	Character string specifying the column name for measured response.
group_col	Optional character string specifying a column for grouping.
log_dose	Logical; if TRUE, dose values are log10-transformed for plotting.
plot	Logical; if TRUE, generates a dose-response plot with fitted 4PL curves.
annotate	Logical; if TRUE, annotates the plot with model parameters and fit metrics.

**Value**

A list containing:

fitted\_parameters Data frame with E\_min, E\_max, EC50, n, RMSE, AIC, and BIC for each group.

data Processed data used for fitting and plotting.

**Author(s)**

Paul Angelo C. Manlapaz

logistic\_5pl

5PL Logistic Dose-Response Model (Emax/Imax, Asymmetric)

---

## Description

Fits pharmacodynamic dose-response data to a 5-parameter logistic (5PL) model using nonlinear least squares regression.

The model can handle **both increasing (Stimulatory / Emax)** and **decreasing (Inhibitory / Imax)** dose-response curves automatically.

The 5PL model extends 4PL by adding an asymmetry factor  $s$ :

$$E = E_{min} + \frac{E_{max} - E_{min}}{(1 + (EC_{50}/D)^n)^s} \quad \text{for increasing curves}$$

$$E = E_{min} + \frac{E_{max} - E_{min}}{(1 + (D/IC_{50})^n)^s} \quad \text{for decreasing curves}$$

Key features: \* Automatically detects increasing vs decreasing responses \*  $E_{min}$  = minimum response (floor) \*  $E_{max}$  = maximum response (ceiling) \*  $EC_{50}/IC_{50}$  = dose producing half-maximal effect \*  $n$  = Hill coefficient (steepness) \*  $s$  = asymmetry factor (skew) \* Skewed sigmoidal curve; reduces bias when the rising and falling slopes are not symmetric around EC50

## Arguments

`data`                    A data frame containing dose-response experimental data.  
`dose_col`                Character string specifying the column name for dose.

response_col	Character string specifying the column name for measured response.
group_col	Optional character string specifying a column for grouping.
log_dose	Logical; if TRUE, dose values are log10-transformed for plotting.
plot	Logical; if TRUE, generates a dose-response plot with fitted 5PL curves.
annotate	Logical; if TRUE, annotates the plot with model parameters and fit metrics.

### Value

A list containing:

`fitted_parameters` Data frame with `E_min`, `E_max`, `EC50`, `n`, `s`, `RMSE`, `AIC`, and `BIC` for each group.

`data` Processed data used for fitting and plotting.

```

---

michaelis\_menten

*Michaelis-Menten Kinetics (Linear Form) with Inhibition Comparison*

---

## Description

Performs Michaelis-Menten kinetic analysis using linearized transformations (Lineweaver-Burk by default) to compare multiple datasets and infer inhibition type.

The function fits linear regressions to transformed data and compares slopes and intercepts across conditions.

Interpretation of inhibition patterns (Lineweaver-Burk):

- Competitive inhibition: Same y-intercept ( $1/V_{max}$ ), increased slope  $\rightarrow$  apparent  $K_m$  increases
- Noncompetitive inhibition: Same x-intercept ( $-1/K_m$ ), increased y-intercept  $\rightarrow V_{max}$  decreases
- Uncompetitive inhibition: Parallel lines  $\rightarrow$  both  $K_m$  and  $V_{max}$  decrease proportionally

## Arguments

data	A data.frame containing concentration and rate data.
conc_col	Column name for substrate or drug concentration.
rate_col	Column name for reaction rate or elimination rate.
group_col	Column indicating different conditions (e.g., inhibitor levels).
transform	Linearization method: "Lineweaver-Burk" (default), "Eadie-Hofstee", or "Hanes-Woolf".
inhibition_type	Expected inhibition type: "competitive", "noncompetitive", "uncompetitive", "multi-inhibition" or "none".
plot	Logical; if TRUE, generates linearized comparison plot.

**Value**

A list containing:

`fitted_parameters` A data frame summarizing linear regression results for each group or condition, including the estimated slope, intercept, coefficient of determination ( $R^2$ ), and derived Michaelis-Menten parameters ( $K_m$  and  $V_{max}$ ) computed according to the selected linear transformation.

`transformed_data` A data frame containing the processed and linearized concentration and rate data (x and y) used for model fitting and visualization, along with the original group labels.

`interpretation` A character string describing the expected inhibition pattern based on the specified `inhibition_type` and the comparison of slopes and intercepts across groups.

---

michaelis\_menten\_nl *Michaelis-Menten Kinetics (Nonlinear Form) with Inhibition Comparison*

---

### Description

Performs Michaelis-Menten kinetic analysis using nonlinear least squares fitting to estimate  $K_m$  and  $V_{max}$  for one or more datasets.

This function fits the standard Michaelis-Menten equation:

$$rate = (V_{max} * concentration) / (K_m + concentration)$$

to each group separately and allows comparison of kinetic parameters across conditions (e.g., inhibitors).

Interpretation of inhibition patterns:

- Competitive inhibition:  $K_m$  increases,  $V_{max}$  unchanged
- Noncompetitive inhibition:  $V_{max}$  decreases,  $K_m$  unchanged
- Uncompetitive inhibition: both  $K_m$  and  $V_{max}$  decrease

### Arguments

data	A data.frame containing concentration and rate data.
conc_col	Column name for substrate or drug concentration.
rate_col	Column name for reaction rate or elimination rate.
group_col	Column indicating different conditions (e.g., inhibitor levels).
inhibition_type	Expected inhibition type: "competitive", "noncompetitive", "uncompetitive", "multi-inhibition" or "none".
plot	Logical; if TRUE, generates nonlinear fit comparison plot.

### Value

A list containing:

- `fitted_parameters` A data frame with estimated nonlinear Michaelis-Menten parameters ( $K_m$  and  $V_{max}$ ) for each group or condition, obtained via nonlinear least squares fitting.
- `raw_data` A data frame containing the processed concentration and rate data used for model fitting and plotting, including group labels.
- `interpretation` A character string summarizing the expected inhibition pattern based on the specified `inhibition_type` and the comparison of  $K_m$  and  $V_{max}$  values across groups.

non_compartmental	<i>Non-Compartmental Analysis (NCA) of Plasma Concentration-Time Data (Linear Form)</i>
-------------------	---

---

### Description

Performs non-compartmental analysis (NCA) on plasma concentration-time data assuming linear pharmacokinetics. Computes area under the curve (AUC) using trapezoidal rule, estimates terminal elimination rate constant ( $k_{el}$ ) by linear regression on the log-linear terminal phase, calculates half-life ( $t_{1/2}$ ), clearance (CL), and volume of distribution (Vd).

### Arguments

data	A data.frame containing plasma concentration-time data.
time_col	Character string indicating the column name for time.
conc_col	Character string indicating the column name for concentration.
dose	Numeric value for the administered dose.
group_col	Optional character string specifying a grouping variable for multiple groups.
terminal_points	Number of last points to use for terminal slope estimation (default = 3).

plot	Logical; if TRUE, plots concentration-time profile and terminal phase regression.
annotate	Logical; if TRUE, annotates plot with PK parameters (only for $\leq 2$ groups).

**Value**

A list containing:

fitted\_parameters Data frame with kel, t1/2, AUC, CL, Vd, and R<sup>2</sup> for each group.

data Processed data used for fitting and plotting.

---

non\_compartmental\_nl    *Non-Compartmental Analysis (NCA) of Plasma Concentration-Time Data (Nonlinear Form)*

---

### Description

Performs non-compartmental analysis (NCA) on plasma concentration-time data, fitting the terminal elimination phase using nonlinear regression of an exponential decay. Computes area under the curve (AUC) using trapezoidal rule, estimates terminal elimination rate constant ( $k_{el}$ ), half-life ( $t_{1/2}$ ), clearance (CL), and volume of distribution (Vd).

### Arguments

data	A data.frame containing plasma concentration-time data.
time_col	Character string indicating the column name for time.
conc_col	Character string indicating the column name for concentration.
dose	Numeric value for the administered dose.
group_col	Optional character string specifying a grouping variable for multiple groups.

terminal_points	Number of last points to use for terminal phase estimation (default = 3).
plot	Logical; if TRUE, plots concentration-time profile and terminal phase fit.
annotate	Logical; if TRUE, annotates plot with PK parameters (only for $\leq 2$ groups).

**Value**

A list containing:

fitted\_parameters Data frame with kel, t1/2, AUC, CL, Vd, and R<sup>2</sup> for each group.  
 data Processed data used for fitting and plotting.

one\_compartment\_iv\_bolus

*One-Compartment IV Bolus Pharmacokinetic Model (Linear)*

---

## Description

Fits plasma concentration-time data to the one-compartment intravenous (IV) bolus pharmacokinetic model. The model assumes instantaneous drug distribution throughout a single, well-mixed compartment and first-order elimination kinetics.

The function performs linear regression on log-transformed plasma concentration versus time to estimate the elimination rate constant ( $k_{el}$ ), elimination half-life ( $t_{1/2}$ ), initial concentration ( $C_0$ ), apparent volume of distribution ( $V_d$ ), and clearance ( $CL$ ). Optional grouping (e.g., formulation, subject) and pH-dependent analysis are supported. Publication-quality plots with fitted regression lines and parameter annotations are generated.

Model:  $C(t) = C_0 * \exp(-k_{el} * t)$

Linearized form:  $\log(C) = \log(C_0) - k_{el} * t$

where:

- $C(t)$  is plasma concentration at time  $t$
- $C_0$  is the initial plasma concentration
- $k_{el}$  is the elimination rate constant

Pharmacokinetic parameters:

- Elimination half-life:  $t_{1/2} = \ln(2) / k_{el}$
- Clearance:  $CL = \text{Dose} / \text{AUC}$
- Volume of distribution:  $V_d = CL / k_{el}$

### Arguments

<code>data</code>	A data frame containing plasma concentration-time data.
<code>time_col</code>	Character string specifying the column name for time.
<code>conc_col</code>	Character string specifying the column name for plasma concentration.
<code>dose</code>	Numeric value specifying the administered IV bolus dose.
<code>group_col</code>	Optional character string specifying a grouping variable (e.g., formulation, subject).
<code>plot</code>	Logical; if TRUE, generates a concentration-time plot with fitted lines.
<code>annotate</code>	Logical; if TRUE, annotates the plot with PK parameters (only if $\leq 2$ groups).

### Value

A list containing:

`fitted_parameters` Data frame with  $C_0$ ,  $k_{el}$ ,  $t_{1/2}$ ,  $V_d$ ,  $CL$ , and  $R^2$ .

`data` Processed data used for fitting and plotting.

 one\_compartment\_iv\_bolus\_nl

*One-Compartment IV Bolus Pharmacokinetic Model (Nonlinear)*

---

## Description

Fits plasma concentration-time data to a one-compartment intravenous (IV) bolus pharmacokinetic model using nonlinear regression. The model assumes instantaneous drug distribution throughout a single, well-mixed compartment and first-order elimination kinetics.

Model parameters are estimated by nonlinear least squares: - Elimination rate constant ( $k_{el}$ ) - Initial plasma concentration ( $C_0$ ) - Apparent volume of distribution ( $V_d = \text{Dose} / C_0$ )

Secondary pharmacokinetic parameters are derived: - Elimination half-life ( $t_{1/2} = \ln(2)/k_{el}$ ) - Clearance ( $CL = k_{el} * V_d$ )

The function supports optional grouping (e.g., subjects, conditions). Publication-quality plots with fitted curves are generated, and annotations summarizing key PK parameters appear in the upper-right corner when  $\leq 2$  groups.

Model:  $C(t) = C_0 * \exp(-k_{el} * t)$

## Arguments

data	A data frame containing plasma concentration-time data.
time_col	Character string specifying the column name for time.
conc_col	Character string specifying the column name for plasma concentration.
dose	Numeric value specifying the administered IV bolus dose.
group_col	Optional character string specifying a grouping variable (e.g., subject, condition).
plot	Logical; if TRUE, generates a concentration-time plot with fitted curves.
annotate	Logical; if TRUE, annotates the plot with PK parameters (only if $\leq 2$ groups).

## Value

A list containing:

fitted\_parameters Data frame with  $C_0$ ,  $k_{el}$ ,  $t_{1/2}$ ,  $V_d$ ,  $CL$ ,  $RMSE$ ,  $AIC$ , and  $BIC$ .

data Processed data used for fitting and plotting.

one\_compartment\_oral *One-Compartment Oral Pharmacokinetic Model (Linear, First-Order Absorption)*

---

### Description

Fits plasma concentration-time data to the one-compartment oral pharmacokinetic model using a linearized approach. The model assumes first-order absorption and first-order elimination.

Model:  $C(t) = (F * Dose * ka / (Vd * (ka - kel))) * (exp(-kel * t) - exp(-ka * t))$

Linearized approximation: Using log-transformed data in the elimination phase ( $t \gg t_{max}$ ),  $\log(C) \approx \log(C_0) - kel * t$

Parameters:

- ka: absorption rate constant
- kel: elimination rate constant
- C0: apparent initial concentration for elimination phase
- t\_half: elimination half-life
- Vd: apparent volume of distribution
- CL: clearance

### Arguments

data	A data frame containing plasma concentration-time data.
time_col	Character string specifying the column name for time.
conc_col	Character string specifying the column name for plasma concentration.
dose	Numeric value specifying the administered oral dose.
group_col	Optional character string specifying a grouping variable (e.g., formulation, subject).
plot	Logical; if TRUE, generates a concentration-time plot with fitted lines.
annotate	Logical; if TRUE, annotates the plot with PK parameters (only if $\leq 2$ groups).

**Value**

A list containing:

`fitted_parameters` Data frame with C0, kel, t\_half, Vd, CL, and R<sup>2</sup>.

`data` Processed data used for fitting and plotting.

one\_compartment\_oral\_nl

*One-Compartment Oral Pharmacokinetic Model (Nonlinear, First-Order Absorption)*

---

## Description

Fits plasma concentration-time data to a one-compartment pharmacokinetic model following oral administration with first-order absorption and first-order elimination. The model assumes that drug absorption from the gastrointestinal tract and systemic elimination are both proportional to the amount of drug present (linear kinetics), and that the body can be represented as a single, well-mixed compartment.

Model parameters are estimated by nonlinear least squares regression for each group (if specified). The primary parameters include the absorption rate constant ( $k_a$ ), elimination rate constant ( $k_{el}$ ), and apparent volume of distribution ( $V_d/F$ ). Model-consistent secondary pharmacokinetic parameters are derived, including time to maximum concentration ( $T_{max}$ ), maximum concentration ( $C_{max}$ ), area under the concentration-time curve (AUC), and apparent clearance ( $CL/F$ ), where  $AUC = Dose / (k_{el} * V_d/F)$  and  $CL/F = k_{el} * V_d/F$ .

The function includes safeguards against numerical instability when  $k_a$  and  $k_{el}$  are similar, enforces positive parameter bounds during fitting, and performs validity checks for the computation of  $T_{max}$  and  $C_{max}$ . Model performance is summarized using root mean squared error (RMSE) and information criteria (AIC and BIC), which are more appropriate than  $R^2$  for nonlinear pharmacokinetic models.

If grouping is specified (e.g., by subject or formulation), the model is fit independently to each group. Groups with insufficient observations trigger a warning, as parameter estimates may be unreliable.

When plotting is enabled, the function generates publication-quality concentration-time plots showing observed data and the corresponding model-predicted curves based on the fitted parameters. Annotations summarizing key pharmacokinetic parameters and model diagnostics are optionally added for one group.

An optional LOESS (locally estimated scatterplot smoothing) curve may be overlaid on the observed data for exploratory visualization only. This smoother is purely descriptive, does not represent any pharmacokinetic mechanism, and should not be interpreted as part of the fitted model. For this reason, LOESS smoothing is disabled by default.

Model:  $C(t) = ((F * Dose * k_a) / (Vd * (k_a - k_{el}))) * [\exp(-k_{el} * t) - \exp(-k_a * t)]$

### Arguments

data	A data frame containing plasma concentration-time data.
time_col	Character string specifying the column name for time.
conc_col	Character string specifying the column name for plasma concentration.
dose	Numeric value specifying the administered oral dose.
group_col	Optional character string specifying a grouping variable (e.g., formulation, subject).
plot	Logical; if TRUE, generates a concentration-time plot with fitted curves.
annotate	Logical; if TRUE, annotates the plot with PK parameters (only if $\leq 2$ groups).

### Value

A list containing:

fitted\_parameters Data frame with  $k_a$ ,  $k_{el}$ ,  $T_{max}$ ,  $C_{max}$ ,  $Vd/F$ ,  $CL/F$ , and  $R^2$ .  
 data Processed data used for fitting and plotting.

sigmoid\_emax

*Sigmoid Emax (Stimulatory Hill Model) for Dose-Response Analysis***Description**

Fits pharmacodynamic dose-response data to the stimulatory Hill (Sigmoid Emax) model using nonlinear least squares regression.

The stimulatory Hill model describes increasing pharmacological effects with increasing dose (or concentration) according to:

$$E = E_0 + \frac{E_{max} \cdot D^n}{EC_{50}^n + D^n}$$

where  $E_0$  is the baseline effect,  $E_{max}$  is the maximum stimulatory effect,  $EC_{50}$  is the dose producing 50  $E_{max}$ , and  $n$  is the Hill coefficient.

This model is appropriate when the observed response increases monotonically with dose.

**Arguments**

data	A data frame containing dose-response experimental data.
dose_col	Character string specifying the column name for dose or concentration.
response_col	Character string specifying the column name for measured response.
group_col	Optional character string specifying a column for grouping.
log_dose	Logical; if TRUE, dose values are log10-transformed for plotting (model fitting uses original dose values).
plot	Logical; if TRUE, generates a dose-response plot with fitted Hill curves.
annotate	Logical; if TRUE, annotates the plot with model parameters and fit metrics (only if <=1 group).

**Value**

A list containing:

fitted\_parameters Data frame with  $E_0$ ,  $E_{max}$ ,  $EC_{50}$ , Hill coefficient ( $n$ ), RMSE, AIC, and BIC values for each group.

data The processed dataset used for model fitting and plotting.

  group_col = "subject",
  log_dose = TRUE
)

```

**Description**

Fits pharmacodynamic dose-response data to the inhibitory Hill (Sigmoid I<sub>max</sub>) model using non-linear least squares regression.

The inhibitory Hill model describes decreasing pharmacological effects with increasing dose (or concentration) according to:

$$E = E_0 - \frac{I_{max} \cdot D^n}{IC_{50}^n + D^n}$$

An equivalent parameterization is:

$$E = E_{min} + \frac{(E_0 - E_{min}) \cdot IC_{50}^n}{IC_{50}^n + D^n}$$

where  $E_0$  is the baseline response,  $I_{max}$  is the maximum inhibitory effect,  $IC_{50}$  is the dose producing 50 inhibition, and  $n$  is the Hill coefficient.

This model is appropriate when the observed response decreases monotonically with increasing dose.

**Arguments**

data	A data frame containing dose-response experimental data.
dose_col	Character string specifying the column name for dose or concentration.
response_col	Character string specifying the column name for measured response.
group_col	Optional character string specifying a column for grouping.
log_dose	Logical; if TRUE, dose values are log10-transformed for plotting (model fitting uses original dose values).
plot	Logical; if TRUE, generates a dose-response plot with fitted Hill curves.
annotate	Logical; if TRUE, annotates the plot with model parameters and fit metrics (only if <=1 group).

**Value**

A list containing:

fitted\_parameters Data frame with E<sub>0</sub>, I<sub>max</sub>, IC<sub>50</sub>, Hill coefficient (n), RMSE, AIC, and BIC values for each group.

data The processed dataset used for model fitting and plotting.

```

## Description

Fits quantal toxicity response data to a logistic dose-response model to estimate the Toxic Dose 50 (TD50), defined as the dose producing toxicity in 50

The model uses binomial logistic regression and supports optional grouping (e.g., sex, species, formulation) and stratification by experimental conditions (e.g., exposure route).

In addition to TD50 estimation, the model provides the following interpretable parameters:

- **Slope:** Represents the steepness of the dose-response curve. A larger slope indicates a rapid increase in toxicity with small increases in dose (narrow tolerance or high population sensitivity), whereas a smaller slope reflects a more gradual response, suggesting greater inter-individual variability in susceptibility.
- **Intercept:** Represents the baseline log-odds of observing toxicity at zero dose. A strongly negative intercept indicates minimal background toxicity, while a positive intercept suggests appreciable toxicity in the absence of administered dose, which may indicate experimental bias or background risk.
- **TD50 95% Confidence Interval:** An approximate 95 interval for the TD50, computed using the delta method. This provides an uncertainty range around the estimated dose causing 50
- **McFadden Pseudo-R<sup>2</sup>:** A likelihood-based measure of model goodness-of-fit that quantifies how much better the fitted model explains the data compared to a null (intercept-only) model. Values between 0.1 and 0.2 indicate acceptable biological fit, while values above 0.3 suggest a strong and reliable dose-response relationship.

The function can generate dose-response plots with fitted curves and annotate TD50, slope, intercept, TD50 confidence intervals, and McFadden pseudo-R<sup>2</sup>.

## Arguments

data	A data frame containing toxicity response data.
dose_col	Character string specifying the dose column.
response_col	Character string specifying the binary toxicity response (0 = no toxicity, 1 = toxic response).
group_col	Optional character string specifying a grouping variable.
condition_col	Optional character string specifying an experimental condition.
plot	Logical; if TRUE, generates dose-response plots.
annotate	Logical; if TRUE, annotates the plot with TD50, confidence intervals, and model parameters (only if <=2 groups).

## Value

A list containing:

fitted\_parameters Data frame with TD50, 95 slope, intercept, and pseudo-R2 values for each group.

data The processed data used for model fitting and plotting.

 two\_compartment\_iv\_bolus

*Two-Compartment IV Bolus Pharmacokinetic Model (Linear)*

---

### Description

Fits plasma concentration-time data following an intravenous (IV) bolus dose using a **log-linear** approximation of a two-compartment pharmacokinetic model.

This function applies linear regression to the logarithm of plasma concentrations versus time to estimate the **terminal elimination phase** parameters. The approach provides an empirical approximation to a biexponential decline but does **not explicitly decompose** the curve into distribution and elimination exponentials.

Under the two-compartment IV bolus model, concentration-time profiles are classically described by:

$$C(t) = Ae^{-\alpha t} + Be^{-\beta t}$$

In this implementation, the terminal log-linear phase is approximated as:

$$\log(C) = \log(C_0) - k_{el} t$$

where  $C_0$  is the extrapolated initial concentration and  $k_{el}$  is the apparent elimination rate constant.

From the fitted log-linear model, secondary pharmacokinetic parameters are derived, including terminal half-life, apparent volume of distribution, and clearance.

### Arguments

data	A data frame with plasma concentration-time data.
time_col	Character string for the time column.
conc_col	Character string for plasma concentration column.
dose	Numeric value specifying IV bolus dose.
group_col	Optional character string specifying grouping variable.
plot	Logical; if TRUE, generates concentration-time plots.
annotate	Logical; if TRUE, annotates plot (only if <=2 groups).

### Value

A list containing:

fitted\_parameters Data frame with  $C_0$ ,  $k_{el}$ ,  $t_{half}$ ,  $V_d$ ,  $CL$ , and  $R^2$  for each group.

data Processed data used for fitting and plotting.

two\_compartment\_iv\_bolus\_nl

*Two-Compartment IV Bolus Pharmacokinetic Model (Nonlinear)*

---

### Description

Fits plasma concentration-time data to a two-compartment intravenous (IV) bolus pharmacokinetic model. The model assumes instantaneous drug administration and distribution between central and peripheral compartments, with first-order elimination.

Model:  $C(t) = A * \exp(-\alpha * t) + B * \exp(-\beta * t)$

where:

- A, B: intercept coefficients
- alpha: distribution rate constant ( $\alpha > \beta$ )
- beta: elimination rate constant

### Arguments

data	A data frame containing plasma concentration-time data.
time_col	Character string specifying the column name for time.
conc_col	Character string specifying the column name for plasma concentration.
dose	Numeric value specifying the administered IV bolus dose.
group_col	Optional character string specifying a grouping variable (e.g., formulation, subject).
plot	Logical; if TRUE, generates a concentration-time plot with fitted curves.
annotate	Logical; if TRUE, annotates the plot with PK parameters (only if $\leq 2$ groups).

### Value

A list containing:

`fitted_parameters` Data frame with biexponential coefficients (A and B), alpha, beta, `t_half_alpha`, `t_half_beta`, and  $R^2$  for each group.

`data` Processed data used for fitting and plotting.

weibull\_model

*Weibull Drug Release Kinetic Model***Description**

Fits experimental cumulative drug release data to the Weibull model using a linearized regression of  $\log(-\log(1 - Mt/MInf))$  versus  $\log(\text{time})$ . The function automatically normalizes cumulative percent drug release to fraction (0-1) by default and removes  $t = 0$ . In addition, the function supports optional grouping variables (e.g., formulation, batch) and optional pH-dependent analysis. It generates publication-quality plots with experimental curves, fitted Weibull straight lines, a shape-parameter interpretation table, and annotations for the scale parameter (alpha), shape parameter (beta), coefficient of determination ( $R^2$ ), and the time required for 50-percent drug release (t50).

Users can toggle 'normalize = TRUE/FALSE' to use fraction (0-1) or raw percent drug release. Normalization is recommended (fraction release) because the model assumes  $0 \leq Mt/MInf \leq 1$ .

Model:  $\log(-\log(1 - Mt/MInf)) = \beta * \log(t) - \beta * \log(\alpha)$

The shape parameter beta indicates release kinetics: - beta = 1 : Exponential (first-order release) - beta < 1 : Parabolic (decelerating release) - beta > 1 : Sigmoidal (accelerating then decelerating)

**Arguments**

data	A data frame containing experimental cumulative percent drug release data.
time_col	Character string specifying the column name for time (minutes).
release_col	Character string specifying the column name for cumulative percent drug release or fraction released.
group_col	Optional character string specifying a grouping variable (e.g., formulation, batch).
pH_col	Optional character string specifying a column containing pH values.
plot	Logical; if TRUE, generates a plot with fitted Weibull release curves.
annotate	Logical; if TRUE, annotates the plot with alpha, beta, $R^2$ , and t50 (only if $\leq 2$ groups).
normalize	Logical; if TRUE (default), normalizes cumulative percent drug release to fraction released (0-1). If FALSE, assumes the input release data are already expressed as fraction released.

**Value**

A list containing:

fitted\_parameters Data frame with Weibull parameters (alpha, beta),  $R^2$ , and t50 for each group.

data Processed data used for model fitting and plotting.

---

zero\_order\_release      *Zero-Order Drug Release Kinetic Model*

---

## Description

Fits experimental cumulative drug release data to a zero-order kinetic model using linear regression. The function supports optional grouping variables (e.g., formulation, batch) and optional pH-dependent analysis. It can generate publication-quality plots with fitted straight lines and annotations for zero-order rate constant ( $k_0$ ), intercept, coefficient of determination ( $R^2$ ), and time required for 50-percent drug release ( $t_{50}$ ).

## Arguments

data	A data frame containing experimental drug release data.
time_col	Character string specifying the column name for time (e.g., minutes or hours).
release_col	Character string specifying the column name for cumulative drug release (typically percentage).

group_col	Optional character string specifying a column name used for grouping (e.g., formulation, batch). Default is NULL.
pH_col	Optional character string specifying a column name containing pH values. If provided, zero-order models are fitted separately for each pH.
plot	Logical; if TRUE, generates a plot of experimental data with zero-order fitted straight lines (default is TRUE).
annotate	Logical; if TRUE, annotates the plot with k0, intercept, R <sup>2</sup> , and t50 values for each group (default is TRUE).

**Value**

A list containing:

fitted\_parameters A data frame with k0, intercept, R<sup>2</sup>, and t50 values for each group or pH condition.

data The processed data used for model fitting and plotting.

**Author(s)**

Paul Angelo C. Manlapaz

**Examples**

```
# Example I: Single formulation
df_1 <- data.frame(
  time = c(0, 15, 30, 45, 60, 90, 120, 150, 180),
  release = c(0, 11.4, 20.8, 30.8, 39.8, 57.8, 72, 84.8, 93.5)
)
zero_order_release(
  data = df_1,
  time_col = "time",
  release_col = "release"
)

# Example II: Two formulations (grouped, not pH-dependent)
df_2 <- data.frame(
  time = rep(c(0, 30, 60, 90, 120, 150), 2),
  release = c(
    0, 18, 35, 55, 72, 88, # Formulation A
    0, 12, 26, 40, 58, 70 # Formulation B
  ),
  formulation = rep(c("Formulation A", "Formulation B"), each = 6)
)
zero_order_release(
  data = df_2,
```

```
time_col = "time",
release_col = "release",
group_col = "formulation"
)

# Example III: pH-dependent release
df_pH <- data.frame(
  time = rep(c(0, 60, 120, 180), 2),
  release = c(0, 40, 75, 95, 0, 30, 60, 80),
  pH = rep(c(7.4, 4.5), each = 4)
)
zero_order_release(
  data = df_pH,
  time_col = "time",
  release_col = "release",
  pH_col = "pH"
)

# Example IV: Two formulations under two pH conditions
df1 <- data.frame(
  time = rep(c(0, 30, 60, 90, 120, 150, 180), 2),
  release = c(
    0, 12, 25, 38, 52, 65, 78, # pH 4.5
    0, 15, 30, 47, 63, 78, 90 # pH 7.6
  ),
  pH = rep(c(4.5, 7.6), each = 7)
)
df2 <- data.frame(
  time = rep(c(0, 20, 40, 60, 80, 100, 120), 2),
  release = c(
    0, 10, 22, 35, 50, 64, 77, # pH 4.5
    0, 14, 28, 45, 61, 76, 88 # pH 7.6
  ),
  pH = rep(c(4.5, 7.6), each = 7)
)
df_all <- rbind(
  cbind(dataset = "Dataset 1", df1),
  cbind(dataset = "Dataset 2", df2)
)
zero_order_release(
  data = df_all,
  time_col = "time",
  release_col = "release",
  group_col = "dataset",
  pH_col = "pH"
)
```
